COLORADO RIVER SALINITY OPERATIONS, JANUARY 1, 2010 THROUGH DECEMBER 31, 2010, UNDER IBWC MINUTE NO. 242

This report presents the results of the operations from January 1 through December 31, 2010 under the agreement with the Republic of Mexico (Mexico) titled *Permanent and Definitive Solution to the International Problem of the Salinity of the Colorado River*. The agreement is incorporated into International Boundary and Water Commission, United States and Mexico (IBWC) Minute No. 242 dated August 30, 1973. Minute No. 242 replaced Minute No. 241 (which replaced Minute No. 218). Operations began on June 25, 1974 under Minute No. 242, immediately following approval of Public Law 93-320 *Colorado River Basin Salinity Control Act* (Act of 1974) on June 24, 1974.

This report is based on United States Section of the IBWC (USIBWC) records on water flows and salinity levels determined jointly by the United States and Mexican Sections of the IBWC, as well as flow-monitoring data from the United States Geological Survey and volume and chemical investigations data from the Bureau of Reclamation. **Exhibit 1** shows the locations referred to in this report. The 2010 records show that the United States (U.S.) operations of the lower Colorado River resulted in compliance with the agreement in IBWC Minute No. 242.

SALINITY DIFFERENTIAL

IBWC Minute No. 242 and Water Deliveries

Point 1 of IBWC Minute No. 242 provides that:

“The United States shall adopt measures to assure that . . . the approximately 1,360,000 acre-feet (1,677,545,000 cubic meters) delivered to Mexico upstream of Morelos Dam, have an annual average salinity of no more than 115 p.p.m. ± 30 p.p.m. U.S. count (121 p.p.m. ± 30 p.p.m. Mexican count) over the annual average salinity of Colorado River waters which arrive at Imperial Dam . . .”

A summary of the “scheduled deliveries” and “actual deliveries” made to Mexico follows in **Table 1**:

Table 1: Summary, Total Deliveries of Colorado River Water to Mexico in 2010		
	Scheduled Deliveries	Actual Deliveries Made
NIB (“at the riverbed above Morelos Dam”)	1,678,235 tcm (1,360,562 af) ¹	1,906,865 tcm (1,545,915 af) ²
SIB (“across the land boundary near San Luis, Arizona,” includes the water flows through the limitrophe of the river below Morelos Dam)	172,000 tcm (139,442 af) ¹	154,688 tcm (125,407 af) ³
Total	1,850,235 tcm (1,500,004 af) ¹	2,061,556 tcm (1,671,324 af)
Other water delivered [arriving] to Mexico in the Limitrophe Section ⁴		211,318 tcm (171,318 af) ⁴

³ Sources: Southerly Land Boundary Combined Flow (East Main Canal Wasteway, West Main Canal Wasteway, Main Drain, 242-Lateral) + 11-Mile Wasteway + 21-Mile Wasteway – Diversion Channel (Diversion Channel is subtracted only for the months of Jan., Oct., Nov., and Dec. when flows are diverted into the Wellton-Mohawk Bypass)

⁴ Source: USIBWC Yuma Field Office calculations. Other water arriving in the limitrophe of the Colorado River not accounted for in scheduled deliveries.

The accumulated volume of Colorado River water recorded at Imperial Dam in 2010 was 6,704,935 tcm (5,435,758 af)⁵. The quantities requested by Mexico to be delivered for 2010 were in accordance with Article 10 of the 1944 Water Treaty. The quantities requested are for deliveries to be made at the riverbed above Morelos Diversion Dam, also referred to as the Northerly International Boundary (NIB), and across the southern land boundary near San Luis, Arizona, also referred to as the Southerly International Boundary (SIB). Deliveries across the SIB include the water flows through the limitrophe of the river below Morelos Dam.

No deliveries⁶ of Colorado River water were made to Mexico at Tijuana, Baja California in 2010. Deliveries to Tijuana are diverted at Parker Dam through an existing pipeline at Otay Mesa in San Diego, California and are calculated into the total deliveries made at NIB. Deliveries made through this diversion are governed by IBWC Minute No. 314 which replaced Minute No. 310 in November 2008. This Minute is intended to address periods of shortages expected to occur over the subsequent five years.

The April 2010 earthquake in the Mexicali Valley, Baja California, Mexico caused damage to Irrigation District 014, Rio Colorado infrastructure in Baja California and Sonora. The earthquake damaged 398 miles of canals in Mexico making it difficult to receive and transport its full allotment of Treaty water. In response to this situation, IBWC Minute No. 318 *Adjustment of Delivery Schedules of Water Allotted to Mexico for the Years 2010 Through 2013 as a Result of Infrastructure Damage in Irrigation District 014, Rio Colorado, Caused by the April 2010 Earthquake in the Mexicali Valley, Baja California* dated December 17, 2010 was established. This Minute allows for the downward adjustment of Treaty deliveries at Mexico's request by a maximum of 260,000 af between the remaining portion of 2010 and December 31, 2013 and subsequent delivery of the water when Mexico is able to make beneficial use of it.

Salinity

Table 2 shows a summary of salinity levels and differentials in the lower Colorado River in 2010.

Table 2: Annual Average Flow-Weighted Salinity at Imperial Dam and Morelos Diversion Dam in 2010		
Waters	U.S. count (ppm)	Mexican count (ppm)
Arriving Upstream of Morelos Diversion Dam at NIB	825	889
Arriving at Imperial Dam	686	745
Salinity Differential	139	144

The U.S. and Mexican counts of the annual average salinity differential for 2010 are within the respective ranges contemplated in Minute No. 242. In recent years, the two countries have worked together to determine the reason for the large difference in the salinity values and differential between the U.S. and Mexican counts. For example, in 2007, the U.S. count of the annual average salinity differential was within the range contemplated in Minute No. 242 while the Mexican count that year and in 2004 were above the Minute No. 242 limit. A bi-national team composed of the IBWC, Bureau of Reclamation, and National Water Commission of Mexico was organized to evaluate sampling methods from collection and analysis to data reporting. Additional data was collected in 2006 and 2007 at Imperial Dam and NIB and analyzed by each nation's respective laboratories. After review of the additional data, laboratory techniques, and methods used in both countries, the bi-national team determined the differences in salinity values to be mostly due to differences in analysis methods and total dissolved solids (TDS) computations. The majority of the difference in salinity values can be attributed to the application of a bicarbonate correction factor used by the U.S.

⁵ Source: Table No. 4 from USIBWC Joint Salinity Report.

⁶ Source: USIBWC Yuma Field Office calculations

laboratory in the TDS by summation calculation. In addition, differences in chloride and sulfate values between U.S. and Mexican laboratories due to differing methods of analysis also contributed to differences in the salinity values. Other contributing factors include the analysis of additional parameters by the U.S. as well as differences in instrumentation used by each country for analysis and their respective levels of detection which introduce sources of error in the salinity calculation. Additionally, an audit performed by the Bureau of Reclamation in 2008 identified a possible source of dilution error caused by the improper conditioning and filtration of samples affecting the U.S. salinity differential. Corrective actions were immediately implemented to remove the dilution error. A full detail of the study results is presented in the joint report titled *Binational Study Regarding the Technical Methods and Joint Monitoring of the Salinity in the Colorado River for the fulfillment of International Boundary and Water Commission Minute No. 242 Between the United States and Mexico Conducted from January 2006 to December 2007*.

Table 3 shows all of the annual average flow-weighted salinity levels and salinity differentials of the water resulting from operations under IBWC Minute No. 242 which began on June 25, 1974.

Exhibit 2, which demonstrates the effect of operations under the Minute, graphs the annual average salinity levels in the water arriving [delivered] at Imperial Dam since 1951 (the first full year of deliveries to Mexico under the 1944 Water Treaty) and at NIB since 1958.

Quantities of United States Bypass Drain Water

The Yuma Desalting Plant, located four miles west of Yuma, was built to reduce the salinity of pumped drainage water from the Wellton-Mohawk Irrigation and Drainage District before the water is returned to the Colorado River. Pending completion and operation of desalting projects, the U.S. adopted an interim measure to achieve the agreed-upon salinity differential. This measure consisted of discharging all Wellton-Mohawk pumped drainage water into the United States Bypass Drain, which conveys these waters to the Santa Clara Slough (Cienega de Santa Clara) on the Gulf of California in Mexico. The water diverted to the United States Bypass Drain is then substituted by an equal volume of other water consisting of drainage return flows above the Northerly International Boundary (NIB) and Colorado River water from upstream storage.

Table 4 shows quantities of United States Bypass Drain water delivered, including the 2010 delivery of 144,892 tcm (117,465 af)⁷, at SIB and substituted for by other water for the deliveries to Mexico under IBWC Minute No. 242 since the Act of 1974. A volume of 227 tcm (184 af)⁸ of Bypass Drain water was discharged back into the Colorado River above SIB during 2010.

DELIVERIES AT THE SOUTHERLY INTERNATIONAL BOUNDARY

Point 1 of Minute No. 242 further provides that:

“The United States will continue to deliver to Mexico on the land boundary at San Luis and in the limitrophe section of the Colorado River downstream from Morelos Dam approximately 140,000 acre-feet (172,689,000 cubic meters) annually with a salinity substantially the same as that of the waters customarily delivered there.”

The annual volumes of water delivered to Mexico on the land boundary at San Luis through the

⁷ Source: USIBWC Yuma Field Office calculations

⁸ Source: USIBWC Yuma Field Office calculations

Sanchez Mejorada Canal and in the limitrophe section of the river below Morelos Dam since Minute No. 242 operations began on June 25, 1974 are shown in **Table 5**. These volumes exclude the Wellton-Mohawk drainage water that was bypassed in accordance with Minute No. 242 (discussed above). Delivery volume made in 2010, which totaled 154,688 tcm (125,407 af)⁹, was less than the annual volume of 172,689 tcm (140,001 af) referred to in IBWC Minute No. 242. The quantity of water to make up the difference was delivered in the bed of the Colorado River above Morelos Dam, as stipulated in Point 1 c) of IBWC Minute No. 242.

Annual Average Flow-Weighted Salinity in the Water Delivered to Mexico in 2010 at SIB

The annual average flow-weighted salinity levels of the water delivered to Mexico at SIB near San Luis under IBWC Minute No. 242 since the Act of 1974 are shown in **Table 6**. The 2010 average salinity of 1,103 ppm was lower than the 37-year average of 1,320 ppm, as well as the average of 1,540 ppm for the 10-year period of 1963-72.

The U.S. intends to continue meeting its legal obligations as described in IBWC Minute No. 242 by continuing to make the land boundary water deliveries with the salinity level required by this Minute.

Southerly International Boundary (SIB) Issues and Resolutions

Beginning in late 1995, Mexico raised objections to peaks in salinity levels and variability of flows in water delivered at SIB. The IBWC addressed these SIB matters through an international task force involving the federal water agencies of each country.

Mexico utilizes the 1944 Water Treaty water diverted at Morelos Dam for irrigation and domestic uses in the Mexicali Valley and conveys some of the water via aqueduct to Tecate and Tijuana. Mexico also uses some of the NIB delivered water, along with water from wells near San Luis, Sonora, for mixing with the drainage water that the U.S. continues to deliver at SIB so that the salinity level of these waters is suitable for farming. Mexico uses this combination of waters to irrigate agricultural land in the area of the Mexicali Valley in Sonora known as the Left Bank Unit. Thus, Mexico was concerned about reduction of crop yields, deterioration of soil quality, and increased water salinity on the Mexican side of the river.

Mexico, in this respect, requested that all its 1944 Water Treaty deliveries be made at NIB. This proposal was not practical to the U.S. because it is impossible to stop drainage flows arriving at SIB and the U.S. continues to have the right to make deliveries at SIB as part of the 1944 Water Treaty volume. Further, this request would require an additional release of stored Colorado River water in the U.S. that is fully appropriated. Finally, there was a need to better understand all the factors that influence increasing soil and groundwater salinity and lower crop yields along the west bank of the Colorado River.

The International Task Force met several times to exchange information on U.S. operations and Mexico's management of the delivered water. The Task Force narrowed the various alternatives for salinity control at SIB to a period of four months of the year (January and October through December) during which up to 8,000 af (9,868 tcm) of drainage water from the Boundary Pumping Plant, which pumps Main Drain water into the Sanchez-Mejorada Canal into Mexico, would be diverted to the United States Bypass Drain. It would be replaced with better quality water from the Minute 242 Well Field, discussed in the next section.

⁹ Source: East Main Canal Wasteway + West Main Canal Wasteway + Main Drain + 242-Lateral - Diversion at SIB + 11-Mile Wasteway + 21-Mile Wasteway.

The Task Force also recommended structural modifications to the water delivery system at the SIB to reduce salinity levels and lessen the variability of flows delivered to Mexico. After examining various alternatives to ameliorate salinity peaks and variations in flows at SIB, the alternative to use variable speed motor controllers on the pumps at the Boundary Pumping Plant was chosen. The variable speed motor controller allows a pump to gradually increase its discharge until it reaches its maximum rate of discharge. If the forebay water surface elevation at the Boundary Pumping Plant does not drop, the variable speed pump will shut down and another pump will start up. If the forebay elevation still does not drop, the variable speed pump will start up again. Then it gradually increases its discharge rate until the forebay elevation drops. This should reduce the size of variation in water deliveries and salinity peaks at SIB.

Additions to the facilities at SIB based on the Task Force recommendations included: the replacement of one pump with a variable speed pump; construction of a bifurcation structure with three sluice gates; construction of a 7,000-foot concrete-lined diversion channel from the Boundary Pumping Plant to the United States Bypass Drain; and a control panel for the operation of all pumps and sluice gates.

All facilities have been completed with the exception of a remotely-operated salinity monitoring and control system. Installation of the original supervisory control and data acquisition (SCADA) system has occurred; however, equipment problems persist and the Bureau of Reclamation continues to evaluate the equipment to ensure it meets project specifications. Implementation of control strategies for the variable speed motor controller is in discussions.

The Yuma Desalting Plant (YDP) has been maintained in ready reserve status since the first part of 1993 when the concrete lining of the United States Bypass Drain was damaged by floodwater from the Gila River and the quantity and quality of flows arriving at NIB made operation of the YDP unnecessary. A 90-day demonstration run of the plant at ten percent of its full capacity was conducted in 2007 by the Bureau of Reclamation which allowed for the evaluation of the operational condition of the plant and design deficiencies. In 2008, the Metropolitan Water District of Southern California, the Southern Nevada Water Authority, and the Central Arizona Water Conservation District initiated discussions with the Bureau of Reclamation regarding an additional Pilot Run of the YDP consisting of operating the plant at one-third capacity of the original design for 365 operating days during a 12 to 18 month period in order to provide sufficient performance and cost data and to assess seasonal variation on the operation of the plant.

The Bureau of Reclamation decided to proceed with the Pilot Run on October 29, 2009 and binational consultations resulted in the signing of IBWC Minute No. 316 *Utilization of the Wellton-Mohawk Bypass Drain and Necessary Infrastructure in the United States for the Conveyance of Water by Mexico and Non-Governmental Organizations of Both Countries to the Santa Clara Wetland during the Yuma Desalting Plant Pilot Run* dated April 16, 2010. Under this agreement, the United States, Mexico, and a binational coalition of non-governmental organizations arranged for the delivery of 30,000 af of water to the Santa Clara Slough wetlands in Mexico to compensate for the reduction in flow and increased salinity from the operation of the YDP, as well as environmental monitoring of the wetland system. From October 2009 through March 2010, the U.S. conveyed their commitment of 10,000 af. Mexico began conveying flows through the bypass canal in the U.S. in April 2010 with the conveyance of 5,011 af by the end of the year. The non-governmental organizations did not convey flows to the Santa Clara Slough in 2010.

The Pilot Run commenced on May 3, 2010 and ceased on March 26, 2011. Greater than 30,000 af of irrigation return flow water was treated at the YDP and included in Treaty deliveries to Mexico, resulting in the conservation of a similar volume of water in Lake Mead. Storage credits for the conserved water were distributed among the water agencies which provided funding for the Pilot Run. Review of the data from the Pilot Run is being conducted by the Bureau of Reclamation and participating water agencies to evaluate potential long-term operation of the plant.

GROUNDWATER – MINUTE NO. 242 WELL FIELD

Point 5 of Minute No. 242 provides that:

“Pending the conclusion by the Governments of the United States and Mexico of a comprehensive agreement on groundwater in the border areas, each country shall limit pumping of groundwater in its territory within five miles (eight kilometers) of the Arizona-Sonora boundary near San Luis to 160,000 acre-feet (197,358,000 cubic meters) annually.”

In 2010, Mexico pumped 117,180 tcm (94,999 af) from its San Luis Mesa Well Field located within five miles (eight kilometers) of the boundary near San Luis. **Table 7** shows the annual quantities pumped by Mexico from its San Luis Mesa field.

The U.S. pumped a total of 61,983.7 tcm (50,250.8 af) within five miles of the boundary, including the Minute 242 Well Field. **Table 8** shows the annual quantities pumped by the U.S. from the Minute 242 Well Field and the total pumpage within five miles of the boundary near San Luis from 1975 through 2010.

The Bureau of Reclamation has constructed 21 wells of the original plan to build up to 35 wells that would eventually be required on the U.S. side of the SIB. Construction of the remaining 14 wells has been deferred until additional water supply needs make it necessary. All of the existing wells are located on the mesa within 5 miles (8 kilometers) of the SIB near San Luis. Water captured from these wells is then delivered to Mexico at the SIB in partial satisfaction of the 1944 Water Treaty as substitution for Main Drain water diverted to the United States Bypass Drain. In 2010, 21 wells were pumped.

CONSULTATIONS AND REGIONAL DEVELOPMENTS

Point 6 of Minute No. 242 provides that:

“ ... the United States and Mexico shall consult with each other prior to undertaking any new development of either the surface or the groundwater resources, or undertaking substantial modifications of present developments, in its own territory in the border area that might adversely affect the other country.”

On June 17, 2010, IBWC Minute No. 317 *Conceptual Framework for U.S.-Mexico Discussions on Colorado River Cooperative Actions* was signed and subsequently approved by the U.S. and Mexican governments. The agreement provides the framework for cooperative comprehensive planning of water management in the Colorado River Basin focusing on the topics of water conservation, identifying new water sources, improving system operations, and identifying water for environmental purposes. In addition to the Binational Core Group and four Work Groups established in 2008 under the U.S.-Mexico Joint Statement to identify Joint Cooperative Actions for management of Colorado River waters in both countries, a Consultative Council will be established under Minute No. 317 to facilitate consideration of the legal, administrative, and policy matters associated with the actions.

The Morelos Dam Sediment Removal Project conducted by the IBWC in 2009 removed a total of 256,977 cubic yards of sediment upstream and downstream of the spillway. On behalf of the U.S., Mexico is conducting the environmental mitigation project for the 15.6 hectares of vegetation cleared during the sediment removal project. A contract with PRONATURA Mexico, A.C. was signed December 6 and work began on December 14, 2010 for the restoration of 40 acres at the Laguna Grande site along the Colorado River in Mexico. Funding is being provided by the USIBWC.

The IBWC worked to address problems with giant salvinia (*Salvinia molesta*) and quagga mussels (*Dreissena bugensis*), two invasive species inhabiting the Lower Colorado River Basin. The Aquatic Nuisance Species Task Force conducted quarterly meetings to discuss the invasive species problem. The Palo Verde Irrigation District continued to treat giant salvinia along the irrigation drains with chemical and biological controls; the giant salvinia has been removed from two of the five reaches under treatment. The presence of giant salvinia is also being reduced in Mexico as a result of control efforts. The Bureau of Reclamation continued research on the quagga mussel colonization in the Lower Colorado River. Quagga mussels have been reported at Imperial Dam, six bays in Senator's Wash, and on a float at the NIB gauge but are not causing maintenance or operational hazards. No quagga mussels were noted at Morelos Dam by the IBWC, but the presence of quagga mussels has been reported in Mexico.

The Bureau of Reclamation completed construction of the Drop 2 Reservoir Storage Project along the All American Canal in September 2010. The reservoir, renamed the Warren H. Brock Reservoir, will be used to capture up to 70,000 af per year of non-storable Colorado River flows below Imperial Dam. Additionally, the Bureau of Reclamation is taking part in the Lower Colorado River Multi-Species Conservation Program through riparian and marsh restoration and enhancement along the Laguna Reach of the Colorado River near Yuma, Arizona.

ACKNOWLEDGMENT

The full cooperation of the United States Geological Survey and the Bureau of Reclamation, as reported herein, is acknowledged with appreciation. This cooperation enabled compliance with the 1944 Water Treaty and with the salinity agreement with Mexico.

Exhibit 1: Lower Colorado River Area Map

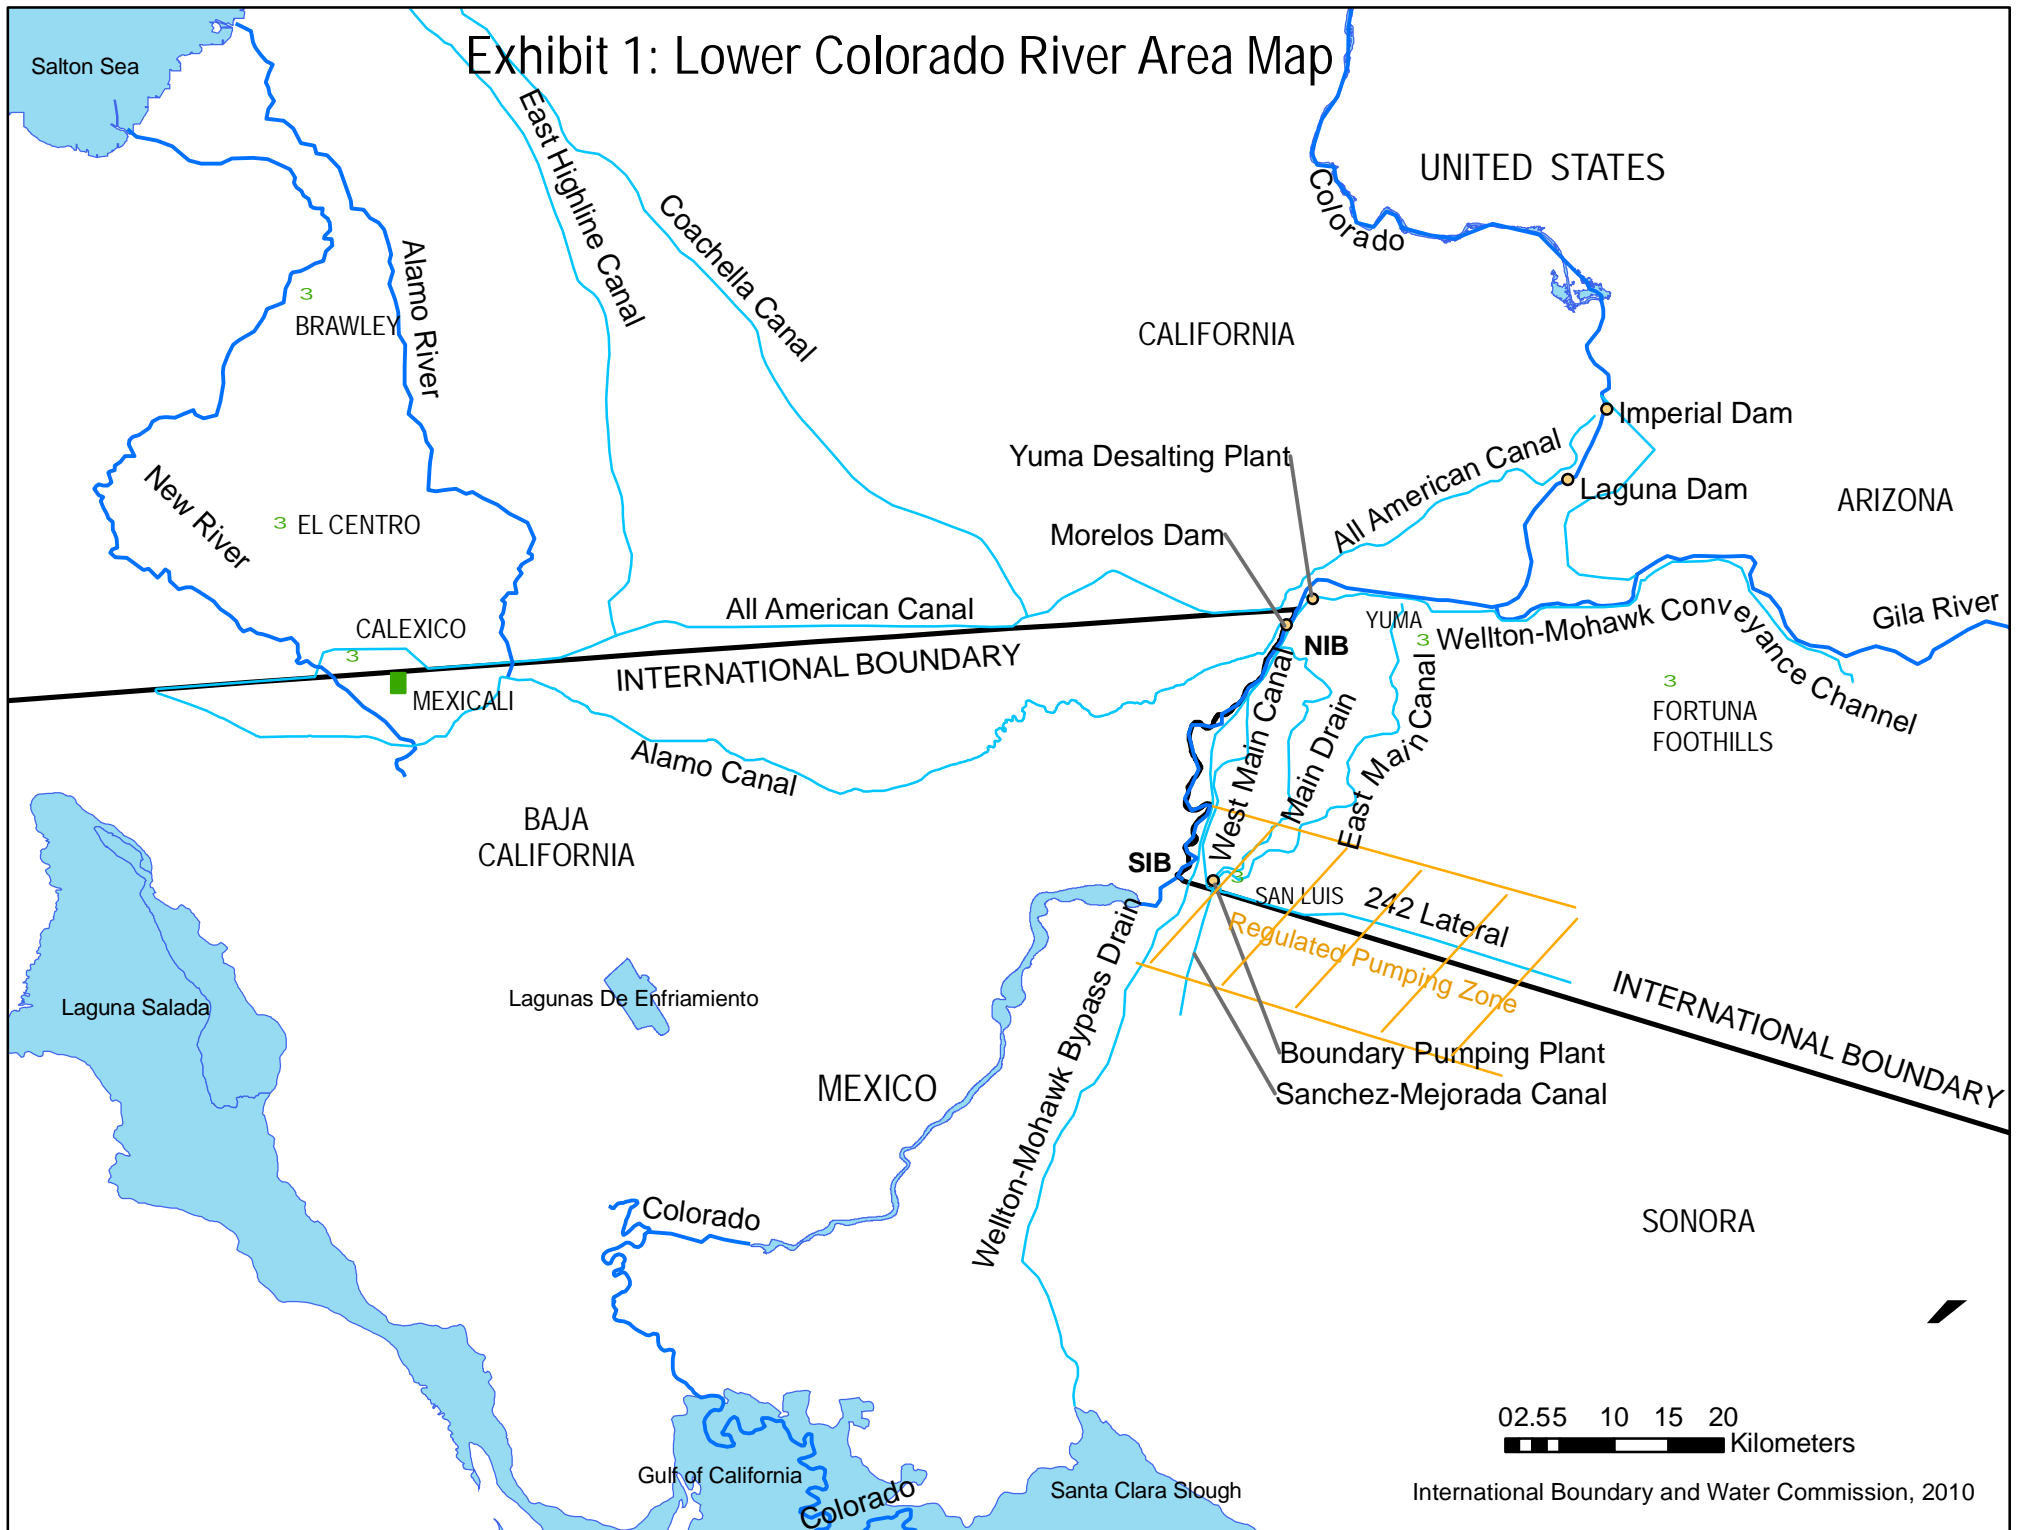

Exhibit 2. Flow-Weighted Annual Average Salinity Levels in the Water Arriving at Imperial Dam Since 1951, and at the Northerly International Boundary (NIB) Since 1958.

¹ Includes undetermined # floodwater from bypass canal levee breaks in U.S.

² Includes Gila River water.

³ Low flows due to damage on drainage canal by Gila River floodwater. Drainage water entered the Gila River, Feb. 21, 1993 - Jan. 18, 1994 and was diluted by high flows.

Table 5. Annual Volumes of Water Scheduled [and/or Actually Delivered] to the Sanchez Mejorada Canal, at the Southerly International Boundary Near San Luis, Arizona, and in the Limitrophe Section of the Colorado River below Morelos Dam [Under IBWC Minute No. 242, since the Colorado River Salinity Control Act, as Amended, became effective on June 24, 1974]

Year	Annual Volume Delivered

2010	117,180	94,999

¹ The reduced pumping was due to excess delivery from the Gila River flood flows.

² No Pumping required due to sufficient flows in the Colorado River.
